Fluctuating Asymmetry as an Indicator of Reproductive Effort in the Leach’s Storm-Petrel (Oceanodroma leucorhoa)

L. E. Michael ’17, R. A. Mauck, Department of Biology, Kenyon College

Background

- Fluctuating asymmetry (FA) is defined as an organism’s deviation from bilateral symmetry in a morphological trait, usually as a consequence of an environmental stressor (Galban 2011, De Coster et al. 2013).
- Fluctuating Asymmetry has been used as a phenotypic measurement of developmental instability (Swaddle 2003).
- Parents balance the energetic investment in young against their own condition. because significant health deterioration can decrease their chances of survival and future reproduction (Erikstad et al. 1997).
- The Leach’s Storm-Petrel (LHSP) is a pelagic seabird that forms long-term pair bonds and lays one egg per year for up to 38 years.
- We measured FA in a population of Leach’s storm-petrels at the Bowdoin Scientific Station that has been studied continuously since 1953.

Acknowledgements

- First and foremost, I would like to thank Professor Robert Mauck for giving me this incredible opportunity and for all of her help with data collection. Finally, I would like to thank the Kenyon Biology Department and Kenyon Summer Science for funding my research and supporting me throughout this process.

Do storm-petrels show FA and can we measure it?

Inducing Feather Growth
- Plucking a feather induces growth of a replacement feather
- Rate of growth shown reflects nutritional condition while grown
- We plucked right and left rectrices from 35 breeding individuals.
- This allowed us to:
  - compare our measurements of feathers in situ against the same feather ex situ.
  - assess our ability to accurately measure in situ morphology.

Measuring Feathers in situ
- With a wing ruler, we measured both original and induced right and left 5th rectrices.

Measuring Feathers ex situ

Feathers measured in situ accurately reflect actual feather length

Figure 1. Ex situ measurements were correlated with in situ measurements. The red line represents measurements for the right side of the bird; the blue line represents measurements for the left side of the bird. Correlation test, r(red) = 0.89, df = 33, p < 0.01, r(blue) = 0.89, df = 33, p < 0.01.

Storm-Petrels show asymmetry in both original and induced feathers

Does FA in storm-petrels reflect reproductive effort?

Measuring FA in the field
- Asymmetry measurements were taken on 91 storm-petrels.
- The induced fifth rectrix (tail feather) was measured on the birds from which an original rectrix was plucked.
- Measurements were taken on left and right wing length, tarsus length, and fifth rectrix length in situ.
- Assumption: FA of original feathers reflect stress during molt (immediately following previous breeding season).
- Assumption: FA of induced feathers reflect stress since original feather was plucked.

Measures of Reproductive Effort
- Assumption: egg size positively correlated with energy allocated to the egg
- Assumption: egg lay date negatively correlated with nutritional condition entering breeding season.
- Assumption: Age and pair bond length may affect energetic demands of incubation due to benefits of experience.

Predictions
- If FA reflects Reproductive Effort, then FA will be:
  - Correlated (+) with egg size and lay date.
  - Correlated (-) with pair bond length and years of site presence.

Weak evidence that FA reflects reproductive effort in storm-petrels

Figure 3. The relationship between in situ tail feather asymmetry values and (A) egg lay date (Pearson’s correlation test, r=0.093, df= 86, p=0.96), (B) pair bond length (Pearson’s correlation test, r=0.0069, df= 40, p=0.96), (C) years of petrel site presence (Pearson’s correlation test, r=0.19, df= 41, p=0.21) and (D) egg volume (Pearson’s correlation test, r=0.26, df= 85, p=0.012).
